Team ID	SWTID-2026-1038
Project Name	Auto Ticket Classification Using Flow Designer
Maximum Marks	5 Marks

Coding & Solution

This section describes the proposed implementation of Auto Ticket Classification using ServiceNow Flow Designer. The solution is intended to classify incoming tickets based on configured conditions, route them to the appropriate category or assignment group, and reduce manual triage effort. Actual results depend on the flow configuration, available ticket fields, and testing in the target ServiceNow instance.

Instructions:

1. Configure a trigger for ticket creation or ticket updates, according to the project requirements.
2. Use Flow Designer conditions and actions to evaluate ticket fields such as short description, category, priority, and service.
3. Update the ticket classification fields and route the ticket to the relevant assignment group where applicable.
4. Test the flow with representative ticket examples, including incomplete or unmatched tickets, before deployment.

Solution Summary

Field	Details
Repository Link / URL	Not provided — add your GitHub / GitLab or project link if available.
Programming Language(s)	ServiceNow Flow Designer configuration; JavaScript only if custom scripting is used.
Framework / Platform	ServiceNow platform and Flow Designer.
Key Features Implemented	Ticket trigger; condition-based classification; category/priority updates; assignment-group routing; flow execution and testing.
Pending / Incomplete Features	To be confirmed after testing. Possible items: handling unmatched tickets, exception paths, and additional classification rules.
Setup / Run Instructions	Open Flow Designer in ServiceNow, configure the trigger and decision conditions, add update/assignment actions, activate the flow, and test using sample tickets.

Code Quality Checklist

For a Flow Designer project, code quality is assessed through clear flow structure, meaningful names, documentation, safe handling of edge cases, successful execution, and version-control or update-set practices where applicable.

S.No	Criteria	Status (Yes / No)
1	Flow is modular and organized into logical steps / reusable subflows where appropriate.	To verify
2	Meaningful names are used for flows, actions, variables, and decision conditions.	To verify
3	Flow descriptions and notes explain the purpose of key conditions and actions.	To verify
4	Fallback handling is defined for missing fields or tickets that do not match a classification rule.	To verify
5	The flow runs without critical errors on representative test tickets.	To verify
6	Changes are tracked using update sets or the team's approved version-control process.	To verify

Additional Notes / Comments:

--

Suggested Test Scenarios

Test Case	Expected Result
Ticket with clear category keywords	Flow applies the configured category and assignment rules.
Ticket with high-priority indicator	Priority follows the configured conditions, if included in the flow.
Ticket with missing or ambiguous details	Flow follows a defined fallback path or leaves the ticket for manual review.
Ticket that does not match any rule	No incorrect classification; default handling or manual triage is applied.
