
Project Executable Files

Date	29 September 2026
Team ID	SWTID-2026-1038
Project Name	Auto Ticket Classification Using Flow Designer
Maximum Marks	3 Marks

Project Executable Files

This section documents the configuration items and supporting files needed to run and demonstrate the Auto Ticket Classification solution built with ServiceNow Flow Designer. The flow is intended to classify incoming tickets using configured conditions, update ticket fields, and route tickets to the appropriate support group. Verify instance-specific settings before submission.

Step 1: Submission Checklist

S.No	Item to Submit	Submitted (Yes / No / NA)
1	Flow Designer flow configuration / screenshots	To be attached
2	Flow trigger and classification conditions	To be attached
3	Actions that update category, priority, assignment group, or other fields	To be attached
4	Test tickets and test results	To be attached
5	Configuration notes / setup guide	Included in this document
6	Required ServiceNow application / plugin access (if applicable)	Verify in instance
7	Environment details and access URL (do not include passwords)	Fill before submission
8	Demo video or walkthrough (if required)	Optional

Note: Flow Designer is configured inside the ServiceNow platform. There may not be a standalone APK, executable binary, or local source-code package. Submit the flow configuration, screenshots, update-set/export information if available, and test evidence according to your course requirements.

File / Configuration Structure

Step 2: File / Folder Structure

Provide an overview of the project artefacts. Adapt the names below to match the items actually created in your ServiceNow instance.

Project artefact	Purpose / contents
Flow Designer flow	Main automation flow triggered when a ticket is created or when configured ticket fields change.
Trigger configuration	Defines the table, trigger timing, and conditions that start classification.
Classification rules	Conditions or decision branches that map ticket descriptions, categories, or keywords to a class.
Update Record action	Writes the selected category, subcategory, priority, or assignment group to the ticket record.
Notification / routing action	Optional action to notify or route the ticket to the relevant support team.
Test cases and evidence	Sample tickets, expected classifications, actual results, and screenshots.
Setup notes / README	Prerequisites, activation steps, test procedure, and known limitations.

Step 3: Deployment / Access Details

Field	Details
ServiceNow instance URL	Enter your authorized instance URL
Platform / hosting	ServiceNow cloud instance (or organization-provided instance)
Flow name	Auto Ticket Classification
Activation status	Verify that the flow is activated before testing
Repository / update set	Add repository URL or update-set name if used
Demo access	Provide approved evaluator access separately; do not place passwords in this PDF
Demo video link	Add link if required

Security reminder: do not include personal passwords, API tokens, or other secret credentials in the submitted PDF.

Run Instructions & Known Issues

Step 4: Run Instructions

Pre-requisites	Access to a ServiceNow development or test instance; permission to view and edit Flow Designer flows; a ticket table such as Incident; and permission to create test records.
Step 1	Sign in to the authorized ServiceNow instance.
Step 2	Open Flow Designer and locate the flow named Auto Ticket Classification (or the configured project flow name).
Step 3	Review the trigger and conditions. Confirm the flow runs for the intended new or updated ticket records.
Step 4	Check the classification branches / decision logic and verify the field values and assignment groups used by each branch.
Step 5	Save and activate the flow if it is not already active and you are authorized to do so.
Step 6	Create a test ticket with a recognizable description, such as a password reset, network issue, or software access request.
Step 7	Confirm the ticket fields and assignment are updated as expected. Review flow execution details if the result is unexpected.
Step 8	Repeat with different ticket types, record the expected and actual outcomes, and capture screenshots for evidence.

Step 5: Known Issues / Limitations

S.No	Known Issue / Limitation	Workaround / Status
1	Unmatched or ambiguous ticket descriptions may not map to a classification rule.	Use a default category or manual review path, if configured.
2	A flow may not run if its trigger conditions are not met or it is inactive.	Check activation, trigger conditions, and execution details.
3	Assignment groups and field choices depend on the target ServiceNow instance.	Verify names and permissions in the project instance.

Submission Notes

Before submission, replace generic flow names with the actual names used in your instance, attach screenshots of the configured flow and successful test executions, and fill in the instance URL or repository link only if permitted by your institution. Test results and deployment details should reflect what was actually run.
